

ELEC 278

Fundamentals of Information Structures

Overview of C

Dr. Jianbing Ni

Department of Electrical & Computer Engineering
Queen's University at Kingston

Data Structure

- Data structure is a way to **store and organize data** in order to facilitate access and modification.
- How can we represent the *completed* contents of this form section in computer memory?

ON 8	
<p>Social insurance number (SIN)</p> <p>____ ____ ____ ____ ____ ____ ____ </p> <p>Date of birth (Year Month Day)</p> <p>____ ____ ____ ____ ____ </p> <p>If this return is for a deceased person, enter the date of death (Year Month Day)</p> <p>____ ____ ____ ____ ____ </p>	<p>Marital status on December 31, 2022:</p> <p>1 <input type="checkbox"/> Married</p> <p>2 <input type="checkbox"/> Living common-law</p> <p>3 <input type="checkbox"/> Widowed</p> <p>4 <input type="checkbox"/> Divorced</p> <p>5 <input type="checkbox"/> Separated</p> <p>6 <input type="checkbox"/> Single</p>

Variables in C

We declare a variable by writing its type followed by its name:

- `int total; // An integer variable named 'total'`
- `char first_initial; // A character variable`
- `int numbers[10]; // An array of 10 numbers`

Variables in C

- Variables are **containers** for storing data values, like numbers and characters.
- A user-defined or a user-readable custom name assigned to a memory location
- **A name of the memory location.**

Address	Values
0xFF000000	total
0xFF000002	first_initial
0xFF000003	number[0]
0xFF000005	number[1]
...	...

Variables in C

- Computer memory consists of many boxes (memory cell), each of which can store some amount of information (usually 1 byte; 256 possible values).
- A program can read or write the contents of any box using its number (**memory address**).
- A variable is just a container that we refer to by some label; that label is just a placeholder for its variable.

Address	Values
0xFF000000	total
0xFF000002	first_initial
0xFF000003	number[0]
0xFF000005	number[1]
...	...

Primitive Data Types in C

The type of the variable describes how the contents of the box(es) referred to by the variable should be interpreted.

- **int** – holds typical integer (at least 16 bits)
- **char** – holds one character (byte)
- **float** – floating point number – at least 32 bits
- **double** – more precise floating point – usually 64 bits

Declaring Variables

```
int j, k, m;
```

```
char p, q, r;
```

```
float f;
```

```
short int a = 5;
```

```
char b = 'Z';
```

```
float pi = 3.14159;
```

```
double abigname99 = -3.7e-4
```

Strings

- A string is a sequence of characters, identified by double quote marks:

```
char str1[12] = "hello";
```

- This really means 6 characters in a row:
'h' 'e' 'l' 'l' 'o' '\0'
- Strings in C are stored in arrays of characters.

```
char str1[12] = "Hello";
```

```
char str2[12] = "World";
```

```
char str3[12];
```

```
strcpy(str3, str1);
```

```
strcat( str1, str2);
```

Arrays

- Arrays are sets of identical data items:
`int g[100]` – 100 integers, `g[0]` to `g[99]`
`char s[50]` – 50 chars, `s[0]` to `s[49]`
`int sin[9];`
`int date_of_birth[8];`
`int date_of_death[8];`

ON 8																					
<p>Social insurance number (SIN)</p> <table border="1"><tr><td></td><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr></table> <p>Date of birth (Year Month Day)</p> <table border="1"><tr><td></td><td></td><td></td><td></td><td></td><td></td></tr></table> <p>If this return is for a deceased person, enter the date of death (Year Month Day)</p> <table border="1"><tr><td></td><td></td><td></td><td></td><td></td><td></td></tr></table>																					<p>Marital status on December 31, 2022:</p> <p>1 <input type="checkbox"/> Married</p> <p>2 <input type="checkbox"/> Living common-law</p> <p>3 <input type="checkbox"/> Widowed</p> <p>4 <input type="checkbox"/> Divorced</p> <p>5 <input type="checkbox"/> Separated</p> <p>6 <input type="checkbox"/> Single</p>

Struct

- A user-defined data type
- used to group items of possibly different types into a single type.
- Syntax of struct:

```
struct structure_name {  
    data_type    member_name1;  
    data_type    member_name2;  
    ....  
};
```

The items in the structure are called its **member**

Struct

```
struct tax_info {  
    int sin[9];  
    int date_of_birth[8];  
    int date_of_death[8];  
    int marital_status;  
};
```

ON 8										
<p>Social insurance number (SIN)</p> <table border="1"><tr><td></td><td></td><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr></table>										<p>Marital status on December 31, 2022:</p> <p>1 <input type="checkbox"/> Married</p> <p>2 <input type="checkbox"/> Living common-law</p> <p>3 <input type="checkbox"/> Widowed</p> <p>4 <input type="checkbox"/> Divorced</p> <p>5 <input type="checkbox"/> Separated</p> <p>6 <input type="checkbox"/> Single</p>
<p>Date of birth (Year Month Day)</p> <table border="1"><tr><td></td><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr></table>										
<p>If this return is for a deceased person, enter the date of death (Year Month Day)</p> <table border="1"><tr><td></td><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr></table>										

Struct

- **Declare struct Variables**

Method 1: If structure_name has been created,

```
struct structure_name variable_name;
```

```
struct structure_name variable_name1, variable_name2;
```

Similar to:
int a, b;

Method 2: Create structure_name and declare variables.

```
struct structure_name {  
    data_type    member_name1;  
    data_type    member_name2;  
    ....  
} variables;
```

Struct

- **Declare struct Variables**

```
struct tax_info my_tax_info;  
struct tax_info Alice_tax_info, Bob_tax_info;  
struct tax_info {  
    int sin[9];  
    int date_of_birth[8];  
    int date_of_death[8];  
    int marital_status;  
} Alice_tax_info, Bob_tax_info, Carlos_family_tax[5];  
% Carlos_family_tax[5] is a struct tax_info array of size 5.
```

Struct

Assign values to structure members

- Curly brackets ‘{}’: initialize all the members

```
Struct tax_info Evetax= {{1,2,3,4,5,6,7,8,9},  
                        {1,9,9,8,0,3,1,3},{2,0,2,2,1,1,1,4}, 5};
```

```
struct Student{  
    char name[50];  
    int class;  
    char section;  
};
```

```
struct Student student1={"Alice" ,1, 'A'};
```

Struct

Access structure members

- Dot ‘.’ : Member operator

Alice_tax_info.sin[9]={1,2,3,4,5,6,7,8,9};

Bob_tax_info.marital_status=4;

```
struct Student {  
    char name[50];  
    int class;  
    char section;  
}student1;  
  
strcpy(student1.name, "Alice");  
student1.class = 1;  
student1.section = 'A';
```

Struct

```
#include <stdio.h>
```

```
#include <string.h>
```

```
struct student  
{  
    int id;  
    char name[20];  
    float percentage;  
};
```

Define the data type

```
int main()  
{
```

Similar to:
`int a, b;`

```
    struct student record;
```

Declare the structure variable

```
    record.id=1;  
    strcpy(record.name, "Raju");  
    record.percentage = 86.5;
```

Assign values to structure members

```
    printf(" Id is: %d \n", record.id);  
    printf(" Name is: %s \n", record.name);  
    printf(" Percentage is: %f \n", record.percentage);
```

Access structure
members

```
    return 0;
```

ELEC278

```
}
```

Struct and Typedef

Typedef: To create an alias name for data types.

Used with structures to simplify the syntax of declaring variables.

```
struct Student {  
    char name[50];  
    int class;  
    char section;  
};  
Main() {  
    Struct Student s1, s2;  
}
```

```
Typedef struct Student {  
    char name[50];  
    int class;  
    char sect  
} Students;  
Main() {  
    students s1, s2;  
}
```

Same as:
int a, b;

Pay attention to differences!

```
struct Student {  
    char name[50];  
    int class;  
    char section;  
} student1;
```

Struct and Typedef

```
#include <stdio.h>
```

```
#include <string.h>
```

```
typedef struct student  
{  
    int id;  
    char name[20];  
    float percentage;  
} Students;
```

Create an alias for structure student

```
int main()
```

```
{
```

```
    Students record;
```

Declare structure variable

```
    record.id=1;
```

```
    strcpy(record.name, "Raju");
```

```
    record.percentage = 86.5;
```

```
    printf(" Id is: %d \n", record.id);
```

```
    printf(" Name is: %s \n", record.name);
```

```
    printf(" Percentage is: %f \n", record.percentage);
```

```
    return 0;
```

```
}
```

Nested Structures

Create structures within a structure

```
struct complex {  
    int imag;  
    float real;  
};  
struct number {  
    struct complex comp;  
    int integers;  
} num1, num2;
```

To assign values to members:

```
num2.comp.imag = 11;  
num2.integers=22;
```

Struct and Pointers

- Create pointers to struct: struct followed by structure name to which the pointer will point to followed by pointer name.

```
struct structure_name *structure_pointer;
```

- To initialize a structure variable, provide the address of the structure variable

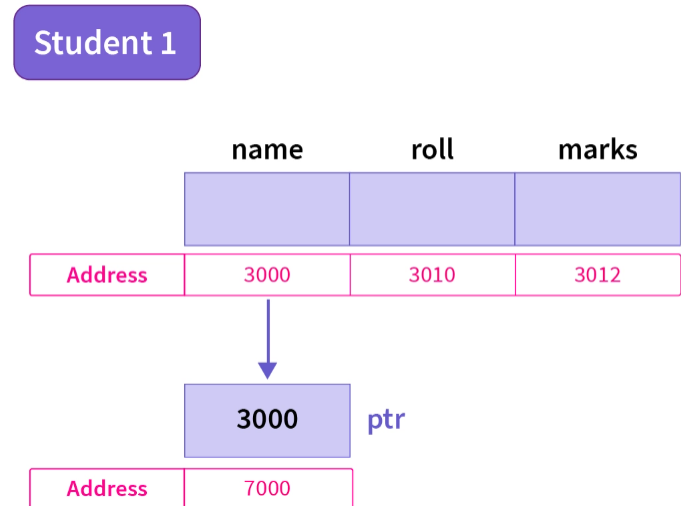

```
structure_pointer = &structure_variable;
```

The structure pointer can be initialized during declaration.

```
struct structure_type *structure_pointer = &structure_variable;
```

Struct and Pointers

```
struct student{  
    char name[10];  
    int roll;  
    int marks;  
};  
  
int main() {  
    struct student Student1;  
    struct student *ptr;  
    ptr=&Student1;  
}
```

Struct and Pointers

Access the Structure Member Using Pointer

- 1. Using asterisk (*) and dot (.) operator

```
#include<stdio.h>
struct Coordinate {
    // declare structure members
    int x,y;
};
int main() {
    struct Coordinate first_point;
    struct Coordinate *cp;
    cp = &first_point;
    (*cp).x = 5;
    (*cp).y = 10;
    printf("First coordinate (x, y) = (%d, %d)", (*cp).x, (*cp).y);
    return 0;
}
```

- cp is a pointer that points to the structure variable first_point
- *cp and first_point are functionally identical

Struct and Pointers

Access the Structure Member Using Pointer

- 2. Using the arrow operator: `pointer_name->member_name`

```
#include<stdio.h>
```

```
struct Student {  
    char name[30];  
    int age;  
    int roll_number;  
};
```

```
int main() {  
    struct Student student_1;  
    struct Student *sp = &student_1;  
    scanf ("%s", sp->name);  
    scanf ("%d", &sp->age);  
    scanf ("%d", &sp->roll_number);  
    printf ("\tName: %s\n", sp->name);  
    printf ("\tAge: %d\n", sp->age);  
    printf ("\tRoll Number: %d", sp->roll_number);  
    return 0;}
```

- `sp` is a pointer that points to the structure variable `student_1`
- `sp->` members access the structure member

Struct and Function

- Method 1: Pass the structure to a function by address.
- The structure can be accessed from called function by its address.

```
#include <stdio.h>
struct student {
    char name[50];
    int roll;
    float marks;
};
void display(struct student* st_obj)
{
    printf("Name: %s\n", st_obj->name);
    printf("Roll: %d\n", st_obj->roll);
    printf("Marks: %f\n", st_obj->marks);
}
int main()
{
    struct student st1;
    display(&st1);
    return 0;
}
```

struct student* st_obj=&st1;

**Function Call By
Reference**

Struct and Function

- Method 2: Pass the structure to a function by value.
- The structure can be accessed from called function by its value.

```
#include <stdio.h>
struct student {
    char name[50];
    int roll;
    float marks;
};
void display(struct student st_obj)
{
    printf("Name: %s\n", st_obj.name);
    printf("Roll: %d\n", st_obj.roll);
    printf("Marks: %f\n", st_obj.marks);
}
int main()
{
    struct student st1;
    display(st1);
    return 0;
}
```

Function Call By Value
